

Number Bases

☰ Chapter No.	6
▼ Status	Completed

▼ Denary (Base 10)

- The digits 0 to 9 are used

▼ Example

4350 (Base 10)

Aa Number in Base 10	☰ 10^3	☰ 10^2	☰ 10^1	☰ 10^0
<u>4350</u>	4	3	5	0

▼ Binary (Base 2)

- Only the digits 0 and 1 are used

▼ Example

- $1110 \text{ (Base 2)} = (1 \times 2^3) + (1 \times 2^2) + (1 \times 2^1) + (0 \times 2^0) = 14 \text{ (Base 10)}$

1110 (Base 2) = 14 (Base 10)

Aa Number in Base 2	☰ 2^3	☰ 2^2	☰ 2^1	☰ 2^0
<u>1110</u>	1	1	1	0

▼ Hexadecimal (Base 16)

- The digits 0 to 9 and the letters A to F are used
- The letters A to F represent 10 (Base 10) to 15 (Base 10) respectively

▼ Example

- $B07A \text{ (Base 16)} = (11 \times 16^3) + (0 \times 16^2) + (7 \times 16^1) + (10 \times 2^0) = 45178 \text{ (Base 10)}$

B07A (Base 16) = 45178 (Base 10)

Aa Number in Base 16	 16^3	 16^2	 16^1	 16^0
<u>B07A</u>	11	0	7	10

▼ Converting Between Number Bases in Python

▼ Converting to Denary

- `int(<x>, <base>)`
- Converts a **string** `<x>` which represents a number in a **certain specified base** into its denary equivalent
- `<base>` refers to the **base** in which the **number represented by the string** `<x>` is originally in

```
#converting the binary number x (string) to its denary equivalent
int(<x>, 2)

#converting the hexadecimal number x (string) to its denary equivalent
int(<x>, 16)
```

▼ Converting from Denary to Binary

- `bin(<x>)`
- Returns a **string** of a binary number with the **prefix "0b"** which indicates that the string refers to a binary number

▼ Converting from Denary to Hexadecimal

- `hex(<x>)`
- Returns a **string** of a hexadecimal number with the **prefix "0x"** which indicates that the string refers to a hexadecimal number
